# Relevance of Cryptography

## Examples of Applied Cryptography

- Phone cards, cell phones, remote controls
- Cash machines, money transfer between banks
- Electronic cash, online banking, secure email
- Satellite TV, pay-per-view TV
- Immobilizer systems in cars
- Digital Rights Management (DRM)
- Cryptography is no longer limited to agents, diplomats, and the military. Cryptography is a modern, mathematically characterized science.
- The breakthrough of cryptography followed the broadening usage of the Internet
- For companies and governments it is important that systems are secure and that

***users (i.e., clients and employees)  
are aware of and understand IT security!***

# Definition Cryptology and Cryptography

**Cryptology** (from the Greek *kryptós*, "hidden," and *lógos*, "word") is the science of secure (or, generally speaking, secret) communication. This security requires that legitimate users, a transmitter and a receiver, are able to transform information into a cipher by virtue of a key – that is, a piece of information known only to them. Although the cipher is inscrutable and often unforgeable to anyone without this secret key, the authorized receiver can either decrypt the cipher to recover the hidden information or verify that it was sent in all likelihood by someone possessing the key.

**Cryptography** was concerned initially with providing secrecy for written messages. Its principles apply equally well, however, to securing data flow between computers or to encrypting television signals. Today, the modern (mathematical) science of cryptology is not just a set of encryption mechanisms. It has since been applied to a broad range of aspects of modern life, including data and message integrity, electronic signatures, random numbers, secure key exchange, secure containers, electronic voting, and electronic money.

# Cryptography – Objectives

- **Confidentiality**

Information can be made effectively unavailable or unreadable for unauthorized individuals, entities, and processes.

- **Authentication**

The receiver of a message can verify the identity of the sender.

- **Integrity**

Integrity ensures that data has not been altered or destroyed in an unauthorized manner.

- **Non-Repudiation**

The receiver can prove that the message he or she received is precisely what the sender sent; the sender will have no means to deny any part of his or her participation.

# The CrypTool Project

- Originated as an awareness program for a large bank (internal training)  
→ **Employee education**
- Developed in cooperation with universities (improvement of education)  
→ **Media didactic approach and standard oriented**
  - 1998 **Project start** – over 40 person-years of effort have since been invested
  - 2000 CrypTool available as **freeware**
  - 2002 CrypTool available on the **Citizen's CD and website of the BSI** (German Information Security Agency)
  - 2003 CrypTool becomes **open source** – hosting by University of Darmstadt (Prof. Eckert)
  - 2007 CrypTool available in German, English, Polish, and Spanish
  - 2008 .NET and Java versions started – hosted by University of Duisburg (Prof. Weis) and SourceForge
  - 2010 CT1 available in fifth language, Serbian; .NET and Java versions to be released
- **Awards**
  - 2004 TeleTrust (TTT Förderpreis / Sponsorship Award) 
  - 2004 NRW (IT Security Award NRW)   
  - 2004 RSA Europe (Finalist of European Information Security Award 2004) 
  - 2008 “Selected Landmark” in initiative “Germany – Land of Ideas” 
- **Developers**
  - Developed by people from companies and universities in many different countries.
  - Currently there are about 50 people working on CrypTool worldwide.  
Additional project members or applicable resources are always appreciated.

# Examples of Early Cryptography (1)

## Ancient encryption methods

- **Tattoo on the shaven head of a slave, concealed by regrown hair**
- **Atbash** (circa 600 B.C.)
  - Hebrew secret language, reversed alphabet
- **Scytale from Sparta** (circa 500 B.C.)
  - Described by Greek historian/author Plutarch (45 - 125 B.C.)
  - The sender and receiver each need a cylinder (such as a wooden rod) with the same diameter
  - Transposition (plaintext characters are re-sorted)

# Examples of Early Cryptography (2)

## Caesar encryption (mono-alphabetic substitution cipher)

- **Caesar encryption** (Julius Caesar, 100 - 44 B.C.)
- Simple substitution cipher

**G**ALLIA EST OMNIS DIVISA ...

Plaintext: ↘

ABCDEF**G**H IJKLMN O PQRSTU VWXYZ

Secret alphabet: ↓

DEFGH**I** JKLMNO PQRSTU VWXYZABC

# Examples of Early Cryptography (3)

## Vigenère encryption (poly-alphabetic substitution cipher)

- **Vigenère encryption** (Blaise de Vigenère, 1523-1596)
- Encryption with a keyword using a key table
- Example  
Keyword: **CHIFFRE**  
Encrypting: **VIGENERE** becomes **XPOJSVVG**
- The plaintext character (V) is replaced by the character in the corresponding row and in the column of the first keyword character (c). The next plaintext character (I) is replaced by the character in the corresponding row and in the column of the next keyword character (h), and so on.
- If all characters of the keyword have been used, then the next keyword character is the first key character.
- **Attack** (via Kasiski test; other tests also exist): Plaintext combinations with an identical cipher text combination can occur. The distance of these patterns can be used to determine the length of the keyword. An additional frequency analysis can then be used to determine the key.

# Cryptography in Modern Times

## Developments in cryptography from 1870-1970

### Classic methods

- are still in use today  
(since not everything can be done by a computer...)
- and their principles of transposition and substitution the foundation of the design of modern algorithms, which combine simpler operations at a bit level (a type of multiple encryption or cipher cascade), use block ciphers, and/or use repeated uses of an algorithm over multiple rounds.

### Encryption becomes

- more **sophisticated**,
- **mechanized** or **computerized**, and
- remains **symmetric**.

# Example from the First Half of the 20th Century

## Mechanical encryption machines (rotor machines)

### Enigma Encryption (Arthur Scherbius, 1878-1929)

- More than 200,000 machines were used in WWII.
- The rotating cylinders encrypt every character of the text with a new permutation.
- The Polish Cipher Bureau broke the pre-war Enigma prototype as early as 1932.
- Based on this work, the later Enigma was broken only with massive effort. About 7000 cryptographers in the UK used decryption machines, captured Enigma prototypes, and intercepted daily status reports (such as weather reports).
- **Consequences of the successful cryptanalysis**  
*"The successful cryptanalysis of the Enigma cipher was a strategic advantage that played a significant role in winning the war. Some historians assert that breaking the Enigma code shortened the war by several months or even a year."*

(translated from [http://de.wikipedia.org/wiki/Enigma\\_%28Machine%29](http://de.wikipedia.org/wiki/Enigma_%28Machine%29) - March 6, 2006)

# Cryptography – Important Insights (1)

## ■ Kerckhoffs' principle (first stated in 1883)

- Separation of algorithm (method) and key e.g. Caesar encryption:  
Algorithm: "Shift alphabet by a certain number of positions to the left"  
Key: The "certain number of positions"
- Kerckhoffs' principle:  
The secret lies within the key and not within the algorithm;  
"security through obscurity" is invalid

## ■ One-Time Pad – Shannon / Vernam

- Theoretically completely unbreakable, but highly impractical (used by the red telephone\*)

## ■ Shannon's concepts: Confusion and Diffusion

- Relation between M, C, and K should be as complex as possible  
(M=message, C=cipher, K=key)
- Every ciphertext character should depend on as many plaintext characters and as many characters of the encryption key as possible
- "Avalanche effect" (small modification, big impact)

## ■ Trapdoor function (one-way function)

- Fast in one direction, not in the opposite direction (without secret information)
- Possessing the secret allows the function to work in the opposite direction (access to the trapdoor)

# Examples of Breaches of Kerckhoffs' Principle

The secret should lie within the key, not in the algorithm

- **Cell phone encryption penetrated** (December 1999)

*"Israeli researchers discovered design flaws that allow the descrambling of supposedly private conversations carried by hundreds of millions of wireless phones. Alex Biryukov and Adi Shamir describe in a paper to be published this week how a PC with 128 MB RAM and large hard drives can penetrate the security of a phone call or data transmission in less than one second. The flawed algorithm appears in digital GSM phones made by companies such as Motorola, Ericsson, and Siemens, and used by well over 100 million customers in Europe and the United States." [...]*

*"Previously the GSM encryption algorithms have come under fire **for being developed in secret away from public scrutiny** -- but most experts say high security can only come from published code. Moran [GSM Association] said "it wasn't the attitude at the time to publish algorithms" when the A5 ciphers was developed in 1989, but **current ones being created will be published for peer review.**"*

<http://www.wired.com/politics/law/news/1999/12/32900>

- **Additional example:** In 1999, Netscape Navigator stored email server passwords using a weak proprietary encryption method.

# Key Distribution Problem

## Key distribution for symmetric encryption methods

If **2 persons** communicate with each other using symmetric encryption, they **need one common secret key**.

If  $n$  persons communicate with each other, then they need  $S_n = n * (n-1) / 2$  keys.

That is:

$n = 100$  persons require

$S_{100} = 4,950$  keys; and

$n = 1,000$  persons require

$S_{1000} = 499,500$  keys.

⇒ A factor of 10 more persons means a factor of 100 more keys.

# Cryptography – Important Insights (2)

Solving the key distribution problem through asymmetric cryptography

## Asymmetric cryptography

- For centuries it was believed that the sender and receiver need to know the same secret.
- New idea: Every person needs a key pair (which also solves the key distribution problem)

## Asymmetric encryption

- “Everyone can lock a padlock or drop a letter in a mail box.”
- MIT, 1977: Leonard Adleman, Ron Rivest, Adi Shamir (well known as RSA)
- GCHQ Cheltenham, 1973: James Ellis, Clifford Cocks (publicly declassified December 1997)

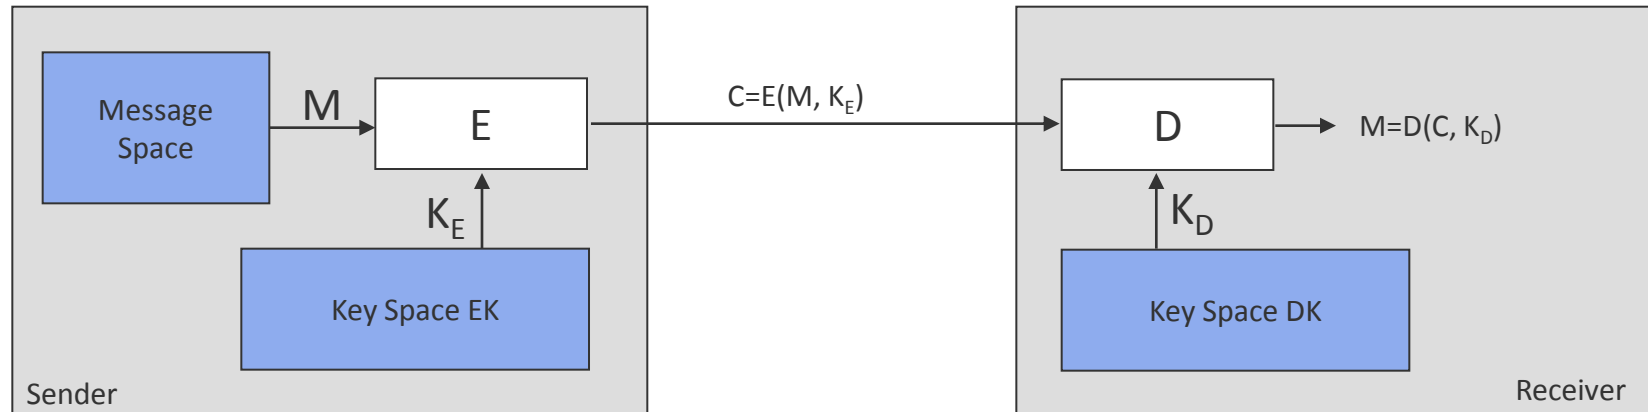

## Key distribution

- Stanford, 1976: Whitfield Diffie, Martin Hellman, Ralph Merkle (Diffie-Hellman key exchange)
- GCHQ Cheltenham, 1975: Malcolm Williamson

*Security in open networks (such as the Internet)  
would be extremely expensive and complex without  
asymmetric cryptography!*

b) Asymmetric Encryption:

# Cryptography – Important Insights (3)

Increasing relevance of mathematics and information technology

- **Modern cryptography** is increasingly based on **mathematics**
  - There are still new symmetric encryption methods, such as AES; these often feature better performance and shorter key length compared to asymmetric methods that are based purely on mathematical problems.
- The security of encryption methods heavily depends on the current state of **mathematics** and **information technology** (IT)
  - Computation complexity (meaning processing effort in relation to key length, storage demand, and data complexity).
    - see RSA: Bernstein, TWIRL device, RSA-160, RSA-768 (CrypTool script, chapter 4.11.3)
  - Major topics in current research:  
Factorization of very large numbers, non-parallelizable algorithms (to counter quantum computers), protocol weaknesses, random generators, etc.).
- Serious mistake: “Real mathematics has no effects on war.”  
(G.H. Hardy, 1940)
- Vendors have realized that **security** is an essential **purchase criterion**.

# Demonstration in CrypTool

- **Statistic Analysis**
- **Encrypting twice is not always better:**
  - Caesar:  $C + D = G$  ( $3 + 4 = 7$ )
  - Vigenère: -  $CAT + DOG = FOZ$   $[(2,0,19)+(3,14,6)=(5,14,25)]$ 
    - "Hund" + "Katze" = "RUGCLENWGYXDATRHNHNMH")
- **Vernam (OTP)**
- **AES (output key, brute-force analysis)**

Appendix

### 1. What is CrypTool?

- Freeware program with graphical user interface
- Cryptographic methods can be applied *and* analysed
- Comprehensive online help (understandable without a deep knowledge of cryptography)
- Contains nearly all state-of-the-art cryptography functions
- Easy entry into modern and classical cryptography
- Not a “*hacker tool*”

### 2. Why CrypTool?

- Originated in an awareness initiative of a financial institute
- Developed in close cooperation with universities
- Improvement of university education and in-firm training

### 3. Target group

- *Core group*: Students of computer science, business computing, and mathematics
- *But also for*: computer users, application developers, employees, high school students, etc.
- *Prerequisite*: PC knowledge
- *Preferable*: Interest in mathematics and/or programming

# Content of the Program Package

English, German,  
Polish, Spanish,  
and Serbian

## CrypTool program

- All functions integrated in a *single* program with consistent graphical interface
- Runs on Win32
- Includes cryptography libraries from Secude, cryptovision, and OpenSSL
- Long integer arithmetic via Miracl, APFLOAT and GMP/MPPIR, lattice-based reduction via NTL (V. Shoup)

## AES Tool

- Standalone program for AES encryption (and creation of self extracting files)

## Educational game

- “Number Shark” encourages the understanding of factors and prime numbers.

## Comprehensive Online Help (HTML Help)

- Context-sensitive help available via F1 for all program functions (including menus)
- Detailed use cases for most program functions (tutorial)

## Script (.pdf file) with background information

- Encryption methods • Prime numbers and factorization • Digital signatures
- Elliptic curves • Public-key certification • Basic number theory • Crypto 2020 • Sage

## Two short stories related to cryptography by Dr. C. Elsner

- “The Dialogue of the Sisters” (features an RSA variant as key element)
- “The Chinese Labyrinth” (number theory tasks for Marco Polo)

# Features (1)

## Cryptography

### Classical cryptography

- Caesar (and ROT-13)
- Monoalphabetic substitution (and Atbash)
- Vigenère
- Hill
- Homophone substitution
- Playfair
- ADFGVX
- Byte Addition
- XOR
- Vernam
- Permutation / Transposition (Rail Fence, Scytale, etc.)
- Solitaire

### Several options to easily comprehend cryptography samples from literature

- Selectable alphabet
- Options: handling of blanks, etc.

## Cryptanalysis

### Attack on classical methods

- Ciphertext only
  - Caesar
  - Vigenère (according to Friedman + Schroedel)
  - Addition
  - XOR
  - Substitution
  - Playfair
- Known Plaintext
  - Hill
  - Single-column transposition
- Manual (program supported)
  - Mono alphabetical substitution
  - Playfair, ADFGVX, Solitaire

### Supported analysis methods

- Entropy, floating frequency
- Histogram, n-gram analysis
- Autocorrelation
- Periodicity
- Random analysis
- Base64 / UU-Encode

# Features (2)

## Cryptography

### Modern symmetric encryption

- IDEA, RC2, RC4, RC6, DES, 3DES, DESX
- AES candidates of the last selection round (Serpent, Twofish, etc.)
- AES (=Rijndael)
- DESL, DESXL

### Asymmetric encryption

- RSA with X.509 certificates
- RSA demonstration
  - For improved understanding of examples from literature
  - Alphabet and block length selectable

### Hybrid encryption (RSA + AES)

- Visualized as an interactive data flow diagram

## Cryptanalysis

### Brute-force attack on symmetric algorithms

- For all algorithms
- Assumptions:
  - Entropy of plaintext is small,
  - Key is partially known, or
  - Plaintext alphabet is known

### Attack on RSA encryption

- Factorization of RSA modulus
- Lattice-based attacks

### Attack on hybrid encryption

- Attack on RSA, or
- Attack on AES (side-channel attack)

# Features (3)

## Cryptography

### Digital signature

- RSA with X.509 certificates
  - Signature as data flow diagram
- DSA with X.509 certificates
- Elliptic Curve DSA, Nyberg-Rueppel

### Hash functions

- MD2, MD4, MD5
- SHA, SHA-1, SHA-2, RIPEMD-160

### Random generators

- Secude
- $x^2 \bmod n$
- Linear congruence generator (LCG)
- Inverse congruence generator (ICG)

## Cryptanalysis

### Attack on RSA signature

- Factorization of the RSA module
- Feasible up to 250 bits or 75 decimal places (on standard desktop PCs)

### Attack on hash functions / digital signature

- Generate hash collisions for ASCII based text (birthday paradox) (up to 40 bits in about five minutes)

### Analysis of random data

- FIPS-PUB-140-1 test battery
- Periodicity, Vitányi, entropy
- Floating frequency, histogram
- n-gram analysis, autocorrelation
- ZIP compression test

# Features (4)

## Visualizations / Demos

- Caesar, Vigenère, Nihilist, DES (all with ANIMAL)
- Enigma (Flash)
- Rijndael/AES (two versions with Flash, one with Java)
- Hybrid encryption and decryption (AES-RSA and AES-ECC)
- Generation and verification of digital signatures
- Diffie-Hellman key exchange
- Secret sharing (with CRT or Shamir)
- Challenge-response method (network authentication)
- Side-channel attack
- Secure email with the S/MIME protocol (with Java and Flash)
- Graphical 3D presentation of (random) data streams
- Sensitivity of hash functions regarding plaintext modifications
- Number theory and RSA cryptosystem (with Authorware)

# Features (5)

## Additional functions

- Different functions for RSA and prime numbers
- Homophone and permutation encryption (Double Column Transposition)
- PKCS #12 import and export for PSEs (Personal Security Environment)
- Hash generation of large files (without loading them)
- Flexible brute force attacks on any modern symmetric algorithm
- ECC demonstration (as Java application)
- Password Quality Meter (PQM) and password entropy
- Manifold text options for the classic ciphers (see [example 24](#))
- And plenty more...

## Vigenère analysis

Demonstration in  
CrypTool

The result of the Vigenère analysis can be manually reworked  
(changing the key length)

### 1. Encrypt the sample file with **TESTETE**

- *“Crypt/Decrypt” \ “Symmetric (classic)” \ “Vigenère”*
- Enter TESTETE ⇒ *“Encrypt”*

Analysis of the encryption results:

- *“Analysis” \ “Symmetric Encryption (classic)” \ “Ciphertext only” \ “Vigenère”*
- Derived key length 7, derived key TESTETE ✓

### 2. Encrypt starting sample with **TEST**

- *“Crypt/Decrypt” \ “Symmetric (classic)” \ “Vigenère”*
- Enter TEST ⇒ *“Encrypt”*

Analysis of the encryption results:

- *“Analysis” \ “Symmetric Encryption (classic)” \ “Ciphertext only” \ “Vigenère”*
- Derived key length 8 – incorrect ✗
- Key length automatically set to 4 (can also be adjusted manually)
- Derived key TEST ✓

## Automated factorization

*Demonstration in  
CrypTool*

### Factorization of a compound number with factorization algorithms

- The algorithms are executed in parallel (multi-threaded)
- Each algorithm has specific advantages and disadvantages; for example, some methods can only determine small factors

# Concepts for a User-Friendly Interface

## 1. Context sensitive help (F1)

- F1 on a selected menu entry shows information about the algorithm/method.
- F1 in a dialog box explains the usage of the dialog.
- These assistants and the contents of the top menus are cross-linked in the online help.

## 2. Copying keys to the key entry dialog

- CTRL-V can always be used to paste contents from the clipboard.
- Stored keys can be copied from ciphertext windows via an icon in the toolbar. A corresponding icon in the key entry dialog can be used to paste the key into the key field. CrypTool uses an **internal keystore**, which is available for every method of the program. (This is particularly helpful for large “specific” keys, such as in homophone encryption.)

# Challenges for Developers (Examples)

## 1. Allow additional functions to run in parallel

- Factorization already uses multi-threading to run several algorithms at once

## 2. High performance

- Locate hash collisions (birthday paradox) or perform brute force analysis

## 3. Consider memory limits

- In particular with regard to the Floyd algorithm (mappings to locate hash collisions) and quadratic sieve factorization

## 4. Time measurement and estimation

- Display remaining time (e.g. while using brute force)

## 5. Reusability / Integration

- Forms for prime number generation
- RSA cryptosystem (switches the view after successful attack from public key user to private key owner)

## 6. Partially automate the consistency of functions, GUI, and online help

(including different languages and the supported Windows OSes: XP, Vista, Win7)

# Examples (1)

## Encryption with RSA

- Basis of the SSL protocol (access to protected websites), among others
- Asymmetric encryption using RSA
  - Every user has a key pair – one public and one private key.
  - Sender encrypts with public key of the recipient.
  - Recipient decrypts with his or her private key.
- Usually implemented in combination with symmetric methods (hybrid encryption): the symmetric key is transmitted using RSA asymmetric encryption/decryption

# Examples (1)

## Encryption using RSA – Mathematical background / algorithm

- Public key:  $(n, e)$  [the modulus  $N$  is often capitalized]
- Private key:  $(d)$

### where

$p, q$  are large, randomly chosen prime numbers with  $n = p * q$ ;

$d$  is calculated under the constraints  $\gcd[\phi(n), e] = 1$ ;  $e * d \equiv 1 \pmod{\phi(n)}$ .

Encryption and decryption operation:  $(m^e)^d \equiv m \pmod{n}$

- $n$  is the modulus (its length in bits is referred to as the key length of RSA).
- $\gcd$  = greatest common divisor.
- $\phi(n)$  is Euler's totient function.

### Procedure

- Transform the message into its binary representation
- Encrypt message blockwise such that  $m = m_1, \dots, m_k$  where for all  $m_j$ :  $0 \leq m_j < n$ ;  
The maximum block size  $r$  should be chosen such that  $2^r \leq n$  (and  $2^{r-1} < n$ )

## Prime number tests – RSA requires the use of very large primes

- Fast probabilistic tests
- Deterministic tests

The prime number test methods can test whether a large number is prime much faster than the known factorization methods can divide a number of similar size into its prime factors.

For the AKS test the GMP / MPIR library (**G**NU **M**ultiple **P**recision Arithmetic Library; **M**ultiple **P**recision **I**ntegers and **R**ationals) was integrated into CrypTool.

## Printing of the current prime number records – Mersenne primes

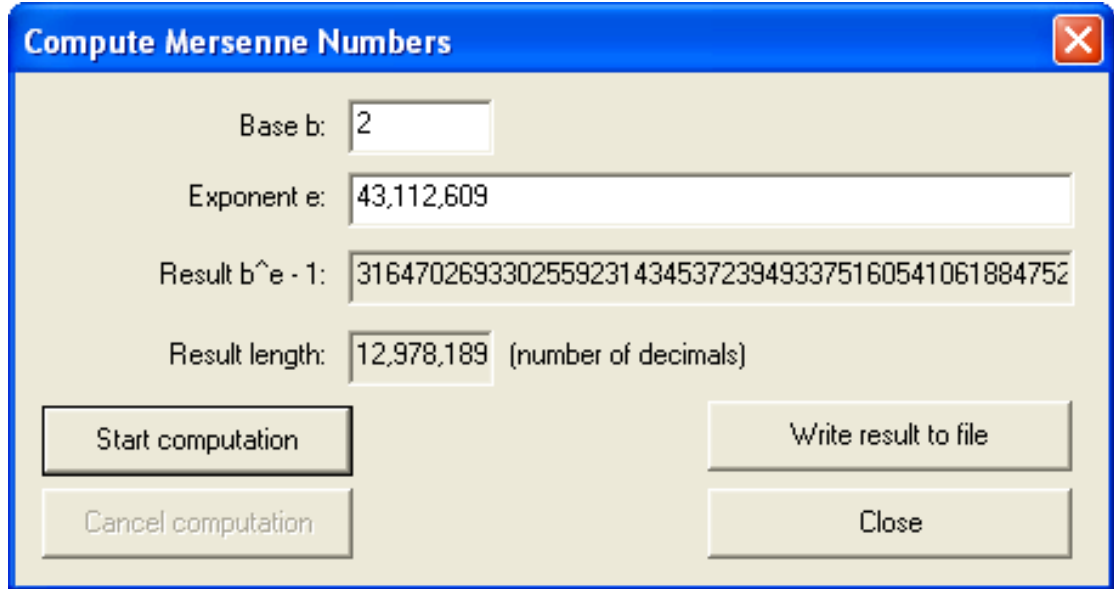

The biggest known primes are so called Mersenne primes.

The currently biggest one has 12,978,189 decimal digits and was discovered in 2008 by the GIMPS project.

The adjoining dialog allows to calculate and write all digits of such numbers very fast.

To do so the APFLOAT library was integrated into CrypTool.

Within the context menu of each input or output field of this dialog you can switch on and off the thousands separator.

Cancel computation      Close

Remark:  $2^{43,112,609} - 1 = 316,470,269 \dots 697,152,511$

Large numbers should not be marked and copied from the “Result” field – because of the performance of the GUI. Please use the button “Write result to file” in order to show the resulting number in its completeness within the CrypTool main window.

# Examples (1)

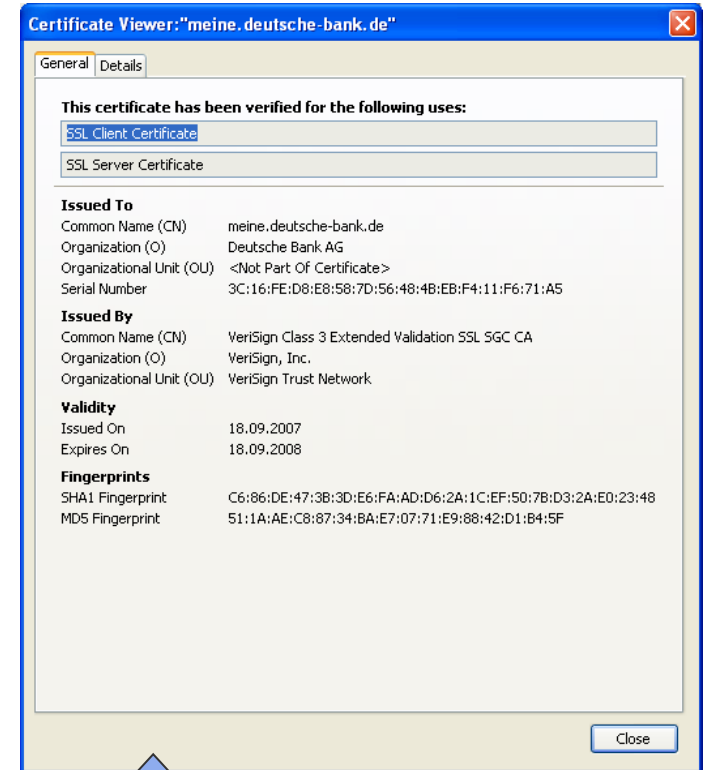

## Hybrid encryption and digital certificates

- Hybrid encryption – **combination of asymmetric and symmetric encryption**
  1. Generation of a random symmetric key (session key)
  2. Session key is transferred – protected by asymmetric key
  3. Message is transferred – protected by session key
- Problem: **man-in-the-middle attacks** – **does the public key of the recipient really belong to the recipient?**
- Solution: digital certificates – **a central instance (e.g., GlobalSign, Telesec, VeriSign, Deutsche Bank PKI), trusted by all users, ensures the authenticity of the certificate and the associated public key (similar to a passport issued by a national government).**
- Hybrid encryption based on digital certificates **is the foundation for all secured electronic communication**
- Internet shopping and online banking
- Secure email

# Examples (1)

## Secured online connection using SSL and certificates

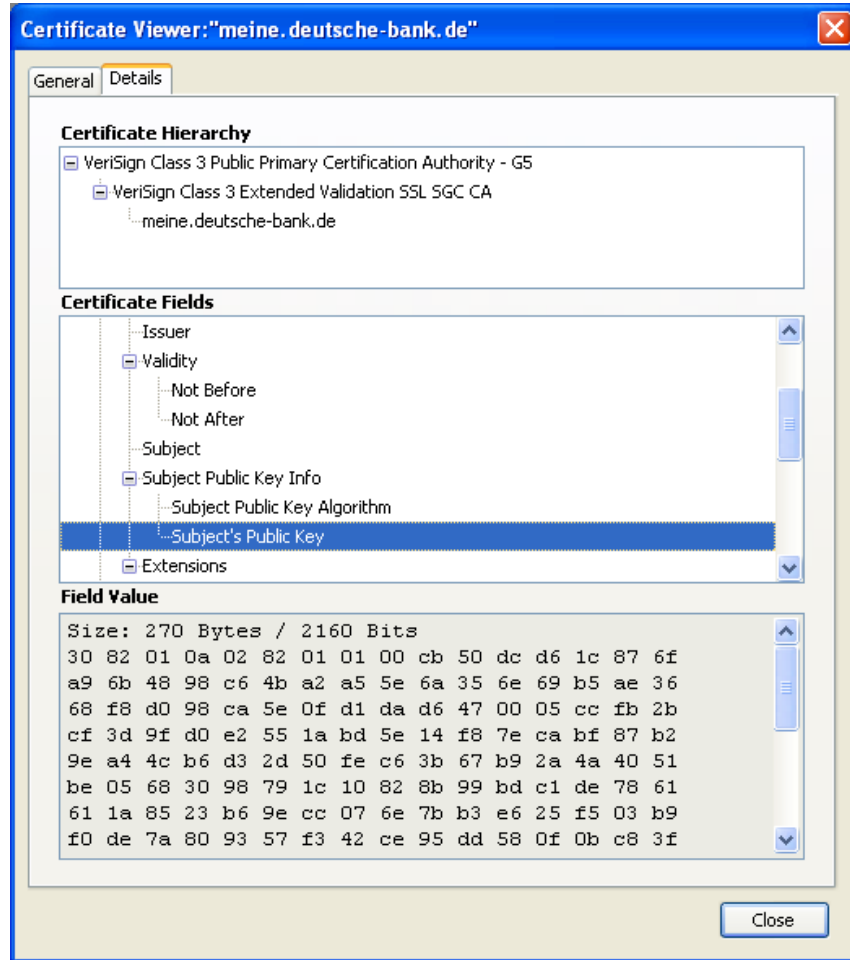

This means that the connection is authenticated (at least on one side) and that the transferred data is strongly encrypted.

# Examples (1)

## Attributes / fields of a certificate

## General attributes / fields

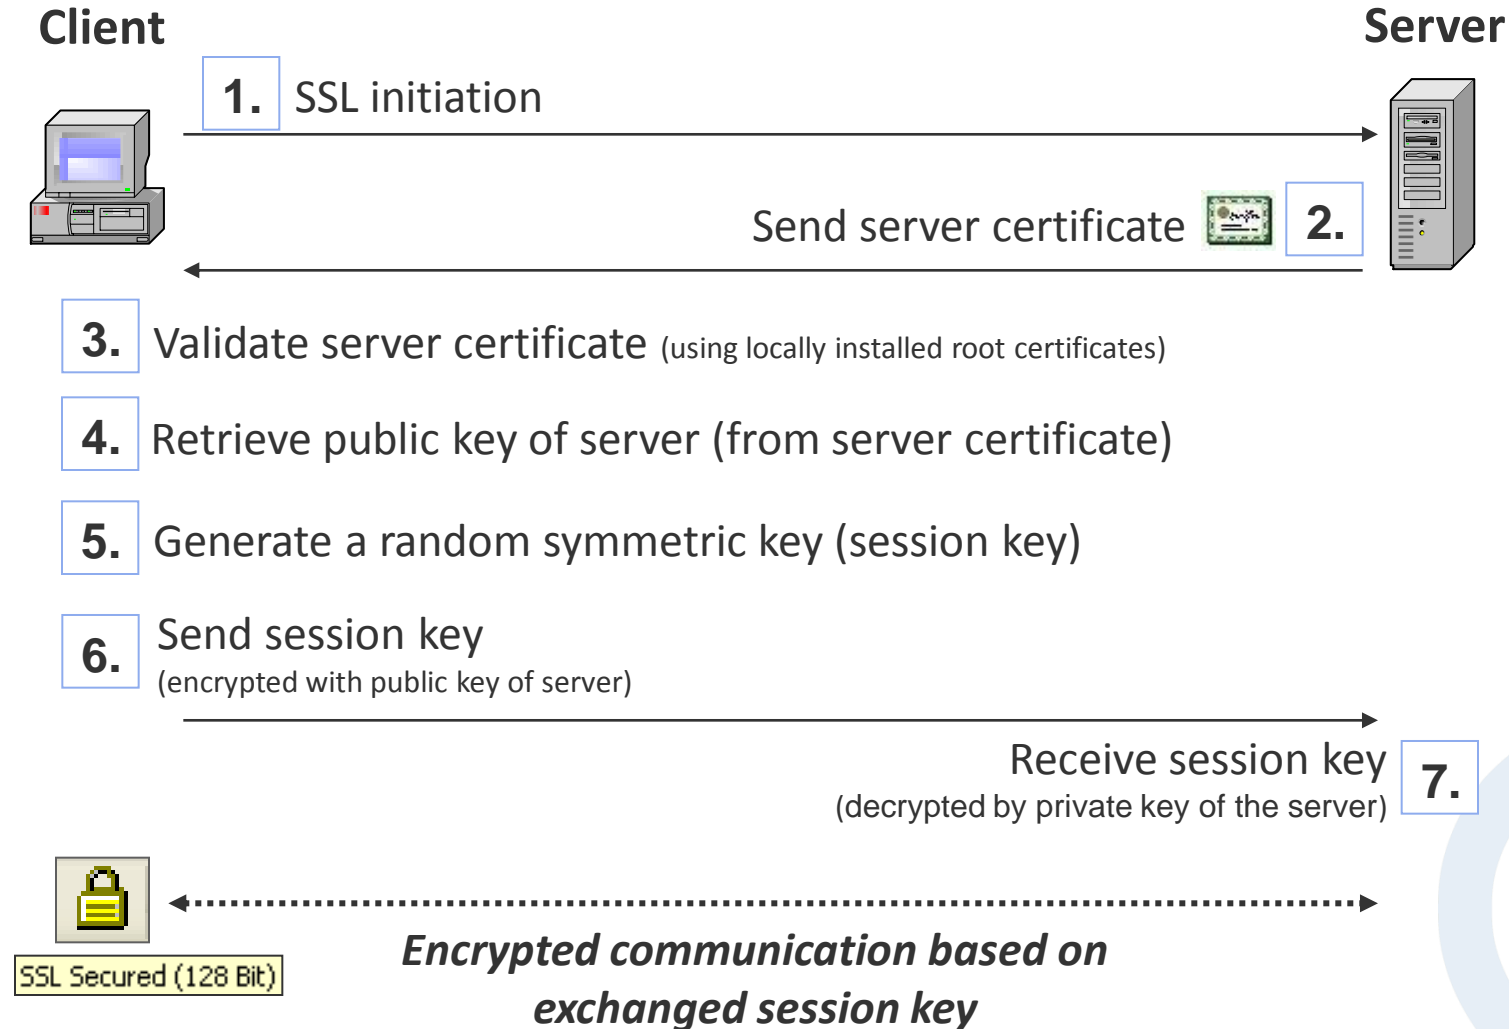

- Issuer (e.g., VeriSign)

- Public key (and method)

## Public Key

# Examples (1)

## Establishing a secure SSL connection (server authentication)

# Examples (1)

## Establishing a secure SSL connection (server authentication)

### General

- The example shows the typical SSL connection establishment in order to transfer sensitive data over the internet (e.g. online shopping).
- During SSL connection establishment only the server is authenticated using a digital certificate (authentication of the user usually occurs through user name and password after the SSL connection has been established).
- SSL also offers the option for client authentication based on digital certificates.

### Remarks on establishing an SSL connection (see previous slide)

- Step 1: SSL Initiation – the characteristics of the session key (e.g. bit size) as well as the symmetric encryption algorithm (e.g. 3DES, AES) are negotiated.
- Step 2: In a multi-level certificate hierarchy, the required intermediate certificates are also passed to the client.
- Step 3: The root certificates installed in the browser's certificate store are used to validate the server certificate.
- Step 5: The session key is based on the negotiated characteristics (see step 1).

# Examples (2)

## Digital signature visualized

### Digital signature

- Increasingly important
  - Equivalent to a handwritten signature (digital signature law)
  - increasingly used by companies, governments, and consumers
- Few actually know how it works

### Visualization in CrypTool

- Interactive data flow diagram
- Similar to the visualization of hybrid encryption

# Examples (3)

## Attack on RSA encryption with short RSA modulus

### Example from Song Y. Yan, *Number Theory for Computing*, Springer, 2000

- Public key
  - RSA modulus **N** = **63978486879527143858831415041** (95 bits, 29 decimal digits)
  - public exponent **e** = **17579**
- Ciphertext (block length = 8):
  - $C_1 = 45411667895024938209259253423$ ,
  - $C_2 = 16597091621432020076311552201$ ,
  - $C_3 = 46468979279750354732637631044$ ,
  - $C_4 = 32870167545903741339819671379$
- This text must be deciphered!

To perform the actual cryptanalysis (revealing the private key), the ciphertext is not actually necessary!

### Solution using CrypTool (further details in the examples section of the online help)

- Enter public parameters into “RSA cryptosystem” (menu: “Indiv. Procedures”)
- Clicking the button “Factorize the RSA modulus” yields the two prime factors  $pq = N$
- Based on that information the private exponent  $d = e^{-1} \bmod (p-1)(q-1)$  can be determined
- Decrypt the ciphertext with  $d$ :  $M_i = C_i^d \bmod N$

**In CrypTool, this attack is only practical for RSA key sizes up to about 250 bits.**

**A successful attack means you could then digitally sign in someone else's name!**

☐ RSA using the private and public key -- or using only the public key

☐ Choose two prime numbers  $p$  and  $q$ . The composite number  $N = pq$  is the public RSA modulus, and  $\phi(N) = (p-1)(q-1)$  is the Euler totient. The public key  $e$  is freely chosen but must be coprime to the totient. The private key  $d$  is then calculated such that  $d = e^{-1} \pmod{\phi(N)}$ .

☒ For data encryption or certificate verification, you will only need the public RSA parameters: the modulus  $N$  and the public key  $e$ .

**Factorization attack**

You may try to factorize the public RSA modulus  $N$  into its primes  $p$  and  $q$ .

## Practical application of cryptanalysis

*Attack on the encryption option in the  
PSION 5 PDA word processing application*

**Starting point: an encrypted file on the PSION**

### Requirements

- Encrypted English or German text
- Depending on method and key length, text of at least 100 bytes up to several kB

### Procedure

- Pre-analysis
    - entropy
    - floating entropy
    - compression test
  - Auto-correlation
  - Automated analysis with classical methods
- } *probably classical  
encryption algorithm*

# Examples (4)

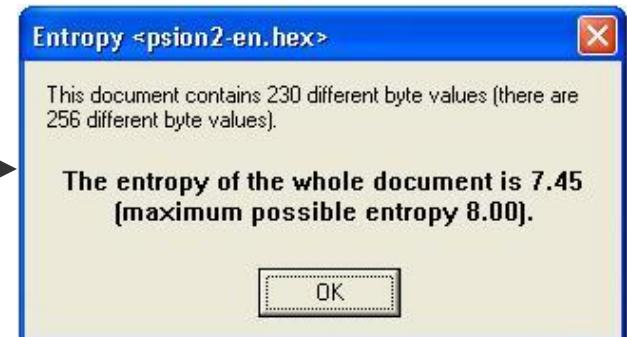

PSION 5 PDA – determine entropy, compression test

Entropy: not all possible values are present, but does not indicate a specific encryption method.

Compressibility: not indicative; a larger value would be a clear indication of weak cryptography

# Examples (4)

## PSION 5 PDA – determine auto-correlation

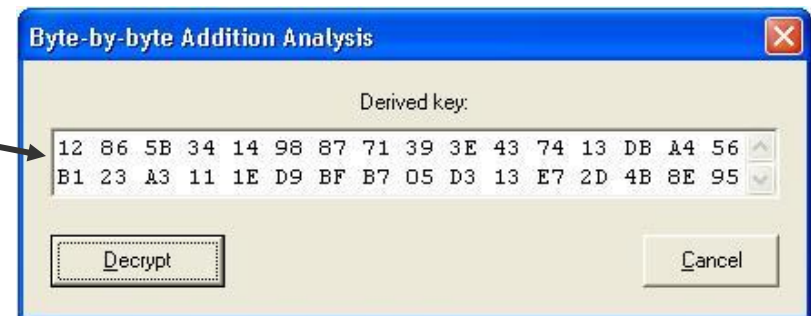

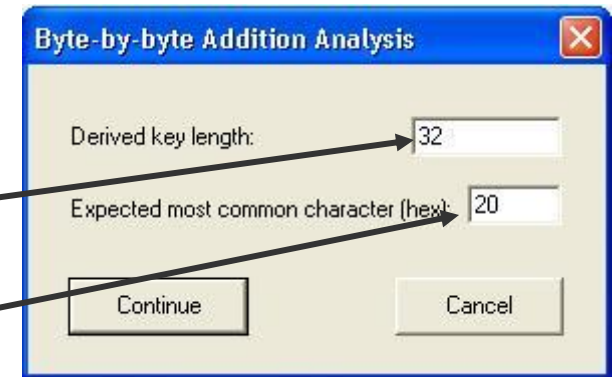

\* The encrypted file is available in Cryptool (see Cryptool\examples\psion-en-enc.hex).

## PSION 5 PDA – automatic analysis

### Automatic analysis using

- **Vigenère: no success**
- **XOR: no success**
- **Byte addition**
  - CrypTool calculates the key length using auto-correlation: 32 bytes
  - The user can choose which character is expected to occur most frequently: the empty space = 0x20 (ASCII code)
  - Analysis calculates the most likely key (based on assumptions regarding distribution)
  - Result: good, but not perfect

# Examples (4)

## PSION 5 PDA – results of automatic analysis

### Results of automatic analysis under the assumption of “byte addition”

- Result is good, but not perfect: 25 out of 32 key bytes correct.
- The key length 32 was correctly determined.

## PSION 5 PDA – determining the remaining key bytes

First, copy the key to the clipboard during automatic analysis.

Then, in the automatic analysis hex dump:

- Determine incorrect byte positions, e.g. 0x1C at position 8
- Guess and write down corresponding correct bytes: “a” = 0x61

Next, in the encrypted initial file hex dump:

- Determine initial bytes from the calculated byte positions: 0x8D
- Calculate correct key bytes with CALC.EXE:  $0x8D - 0x61 = 0x2C$

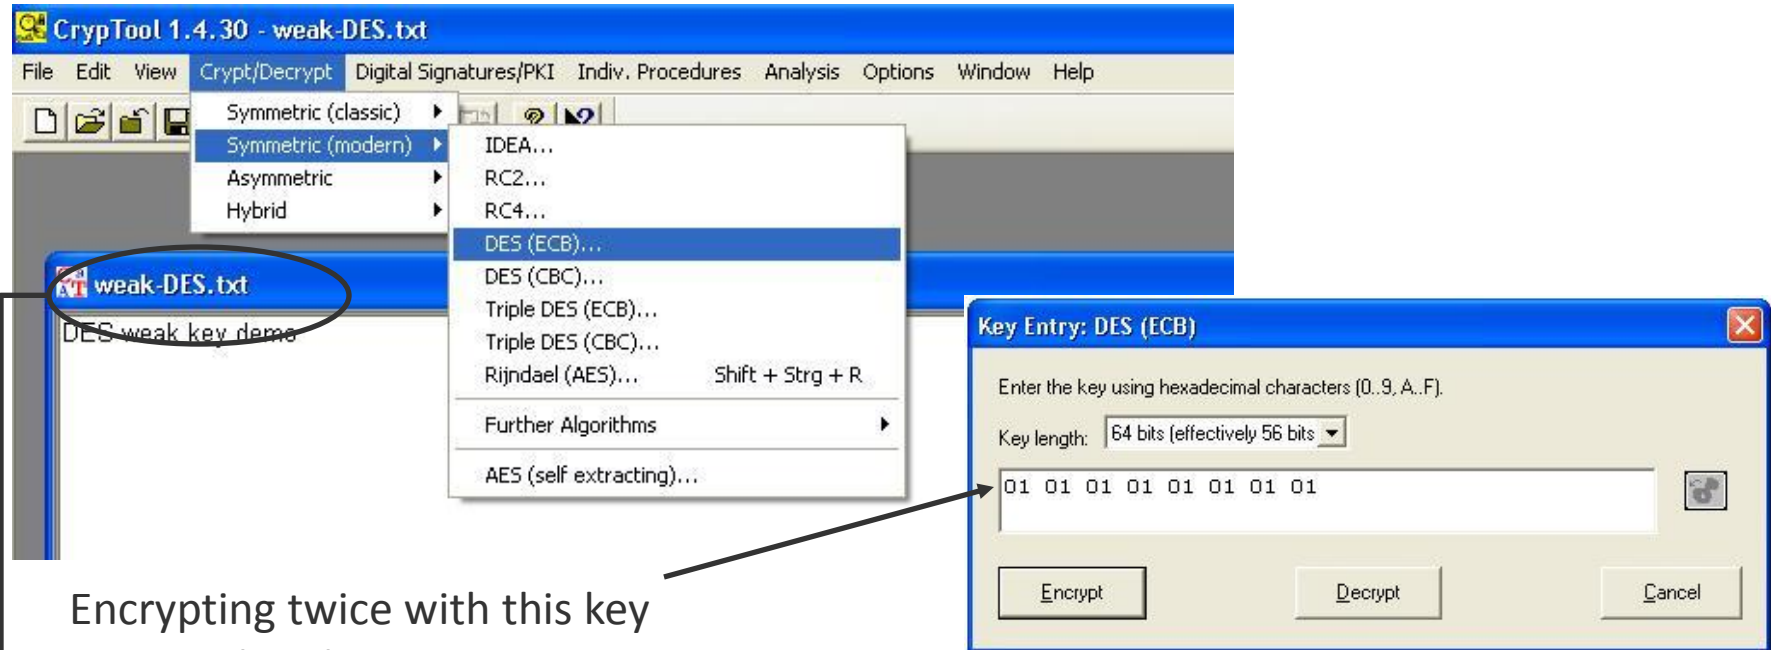

Finally, get the key from the clipboard:

- Correct 12865B34149887**2C**393E437413DBA456B123A3111ED9BFB705D313E72D4B8E95

## Attack on digital signature – idea (I)

**Attack on the digital signature of an ASCII text by means of a hash collision search.**

### Idea:

- ASCII texts can be modified by changing/inserting **non-printable** characters without changing the visible content
- Modify two texts in parallel until a hash collision is found
- Exploit the birthday paradox (birthday attack)
- Generic attack applicable to all hash functions
- Can be parallelized across many machines (not implemented in CrypTool)
- Implemented in CrypTool as part of the bachelor thesis  
*“Methods and Tools for Attacks on Digital Signatures”* (German), 2003.

### Concepts :

- Mappings
- Modified Floyd algorithm (constant memory consumption)

# Examples (7)

## Attack on digital signature – idea (II)

1. **Modification:** starting from a message  $M$  create  $N$  different messages  $M_1, \dots, M_N$  with the same “content” as  $M$ .
2. **Search:** find modified messages  $M_i^H$  and  $M_j^S$  with the same hash value.
3. **Attack:** the signatures of those two documents  $M_i^H$  and  $M_j^S$  are the same.

We know from the birthday paradox that for hash values of bit length  $n$ :

- search collision between  $M^H$  and  $M_1^S, \dots, M_N^S$ :
- search collision between  $M_1^H, \dots, M_N^H$  and  $M_1^S, \dots, M_N^S$ :

$$N \approx 2^n$$

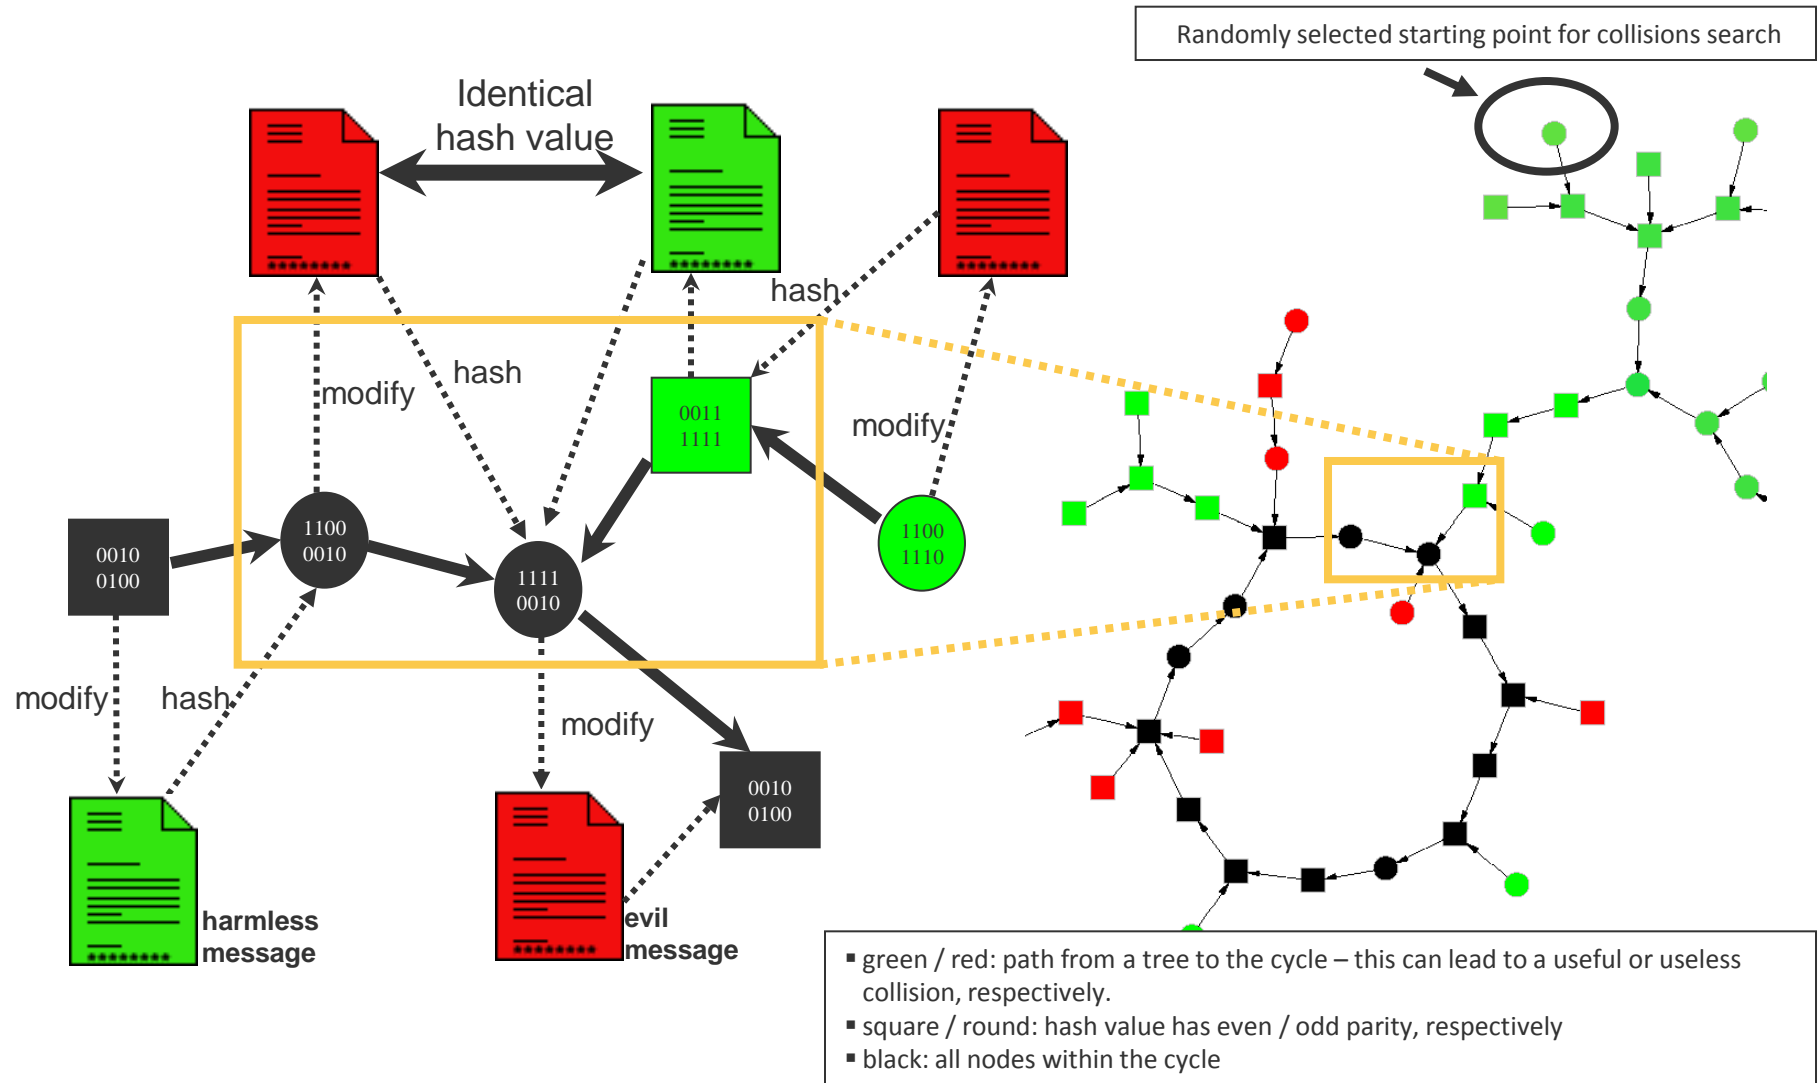

$$N \approx 2^{n/2}$$

## Floyd Algorithm: Meet within the cycle

-  start / collision
-  cycle
-  increment 1
-  increment 2

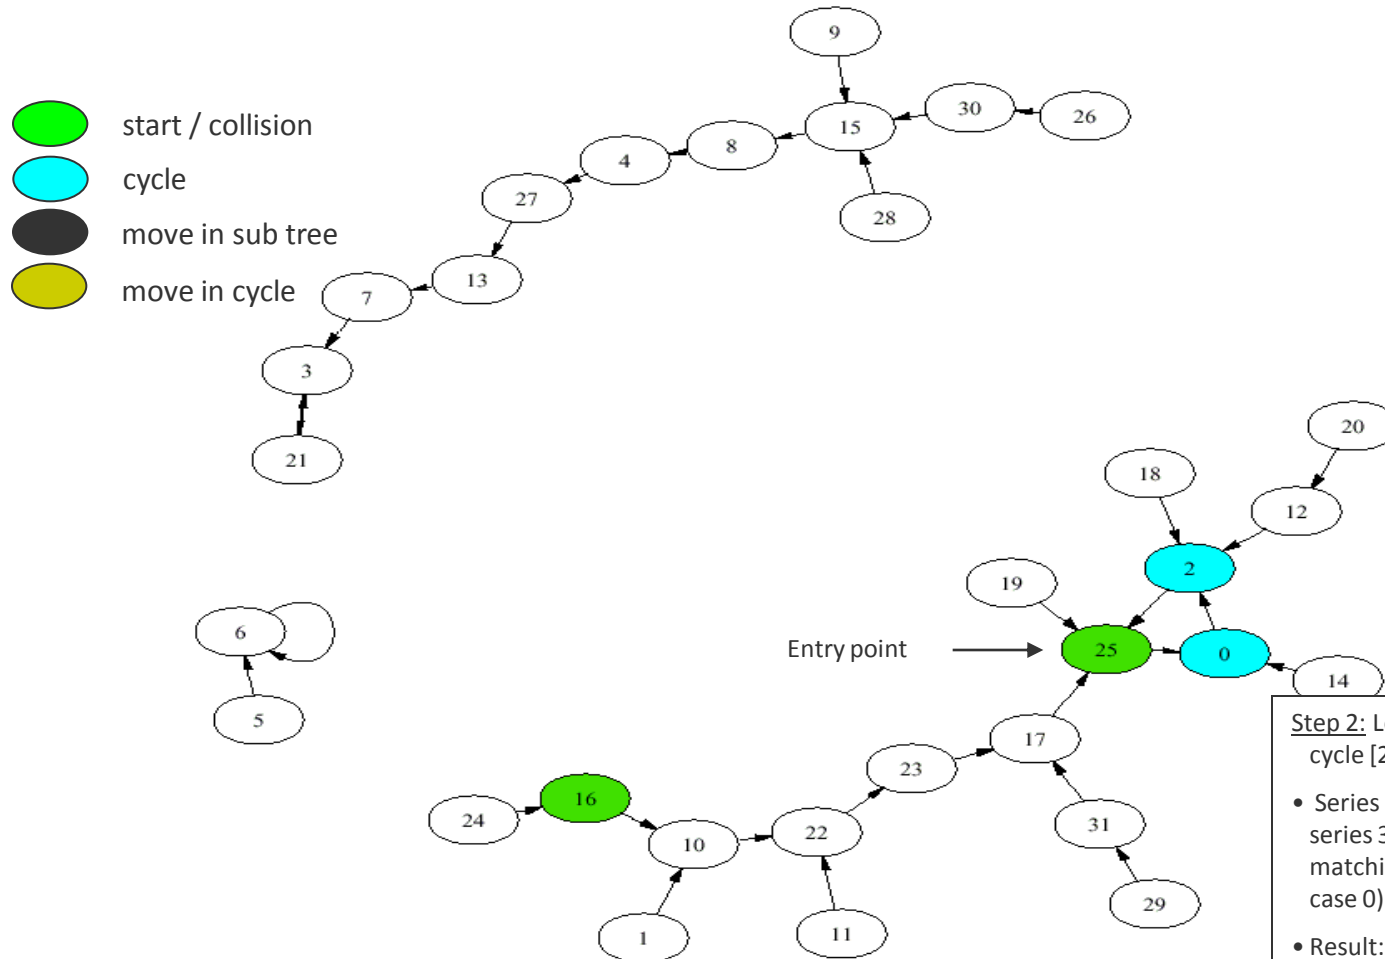

**Example:**  
**Function graph with**  
**32 nodes**

Step 1: Locate matching point within cycle:

- Two series with identical starting point [16]: one series with increment 1, the other with increment 2.
- Result s(based on graph theory):
  - both series always end up in a cycle.
  - both series match in a node within the cycle (in this case 0).

## Step into cycle (extension of Floyd): Find entry point

Step 2: Locate entry point of series 1 in the cycle [25]:

- Series 1 starts again from starting point; series 3 with an increment of 1 starts at matching point within the cycle (in this case 0).
- Result: The series (1 and 3) match in cycle entry point of series 1 (in this case 25)
- The predecessors (in this case 17 and 2) result in a hash collision.

# Birthday Paradox Attack on Digital Signature

## Examination of Floyd algorithm

- Visual and interactive presentation of the Floyd algorithm (“Moving through the mapping” into a cycle).
- Adaptation of the Floyd algorithm for a digital signature attack.

**Starting point**

**Good collision**

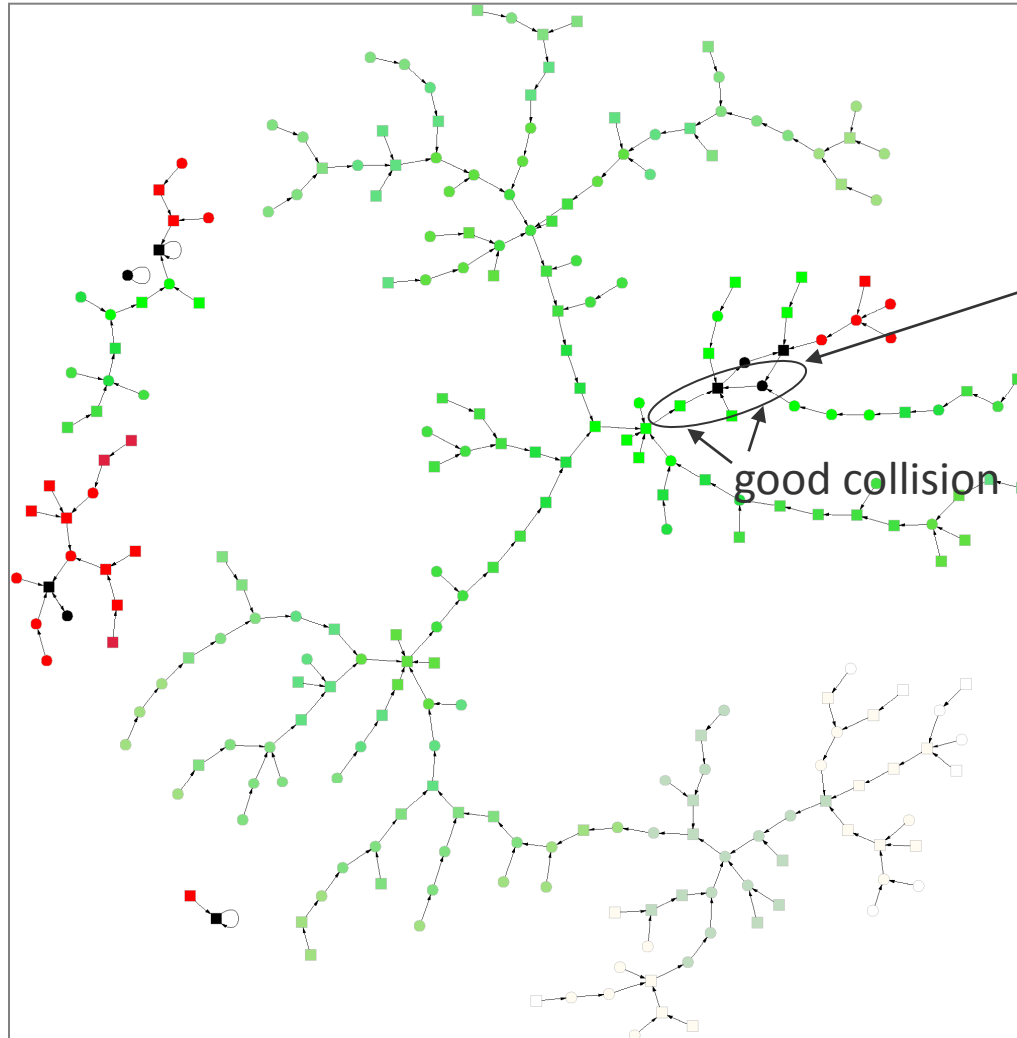

**Bad collision**

\*The Floyd algorithm is implemented in CrypTool, but the visualization of the algorithm has not yet been implemented.

# Examples (7)

## Attack on digital signature

An example of a **“good” mapping** (nearly all nodes are green). In this graph almost all nodes belong to a big tree, which leads into the cycle with an even hash value and where the entry point predecessor within the cycle is odd. That means that the attacker finds a useful collision for nearly all starting points.

## Attack on digital signature: results

The first 32 bits of the hash values are identical.

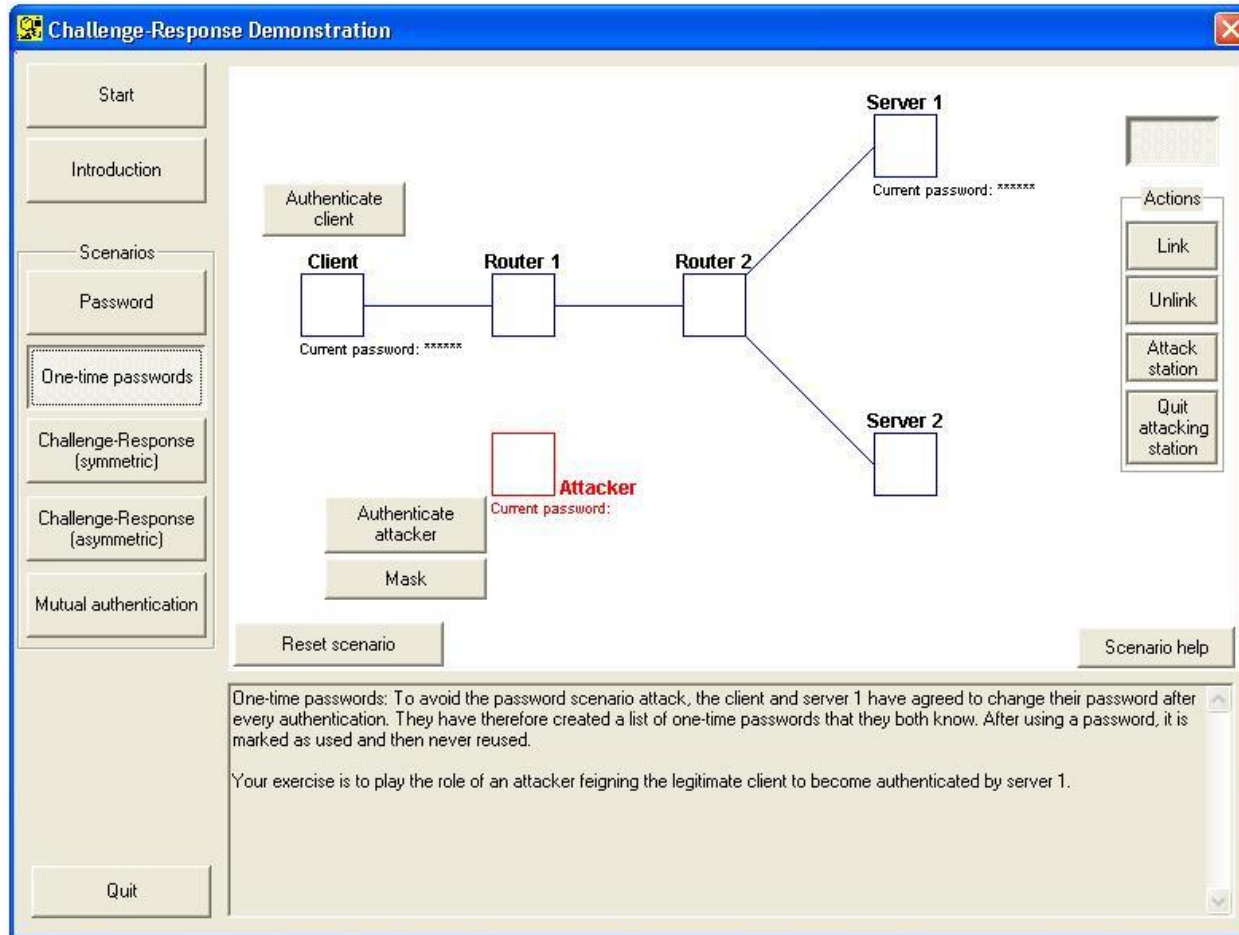

## Experimental results

- A 72-bit *partial collision* (i.e., the first 72 hash value bits are identical) was found in a couple of days using a single PC.
- Today, signatures with hash values of 128 bits or less are vulnerable to a massive parallel search!
- It is therefore recommended to use hash values with a length of at least 160 bits.

In addition to the interactive tool, CrypTool also includes a command-line feature to execute and log the results for entire sets of parameter configurations.

## Side channel attack concept

**Ulrich Kuehn:** “*Side-channel attacks on textbook RSA and ElGamal encryption*”, 2003

**Prerequisites** [CCA (Chosen-ciphertext attack) against deciphering oracle]

- RSA encryption:  $C = M^e \pmod{N}$  and decryption:  $M = C^d \pmod{N}$ .
- 128-bit session keys (in  $M$ ) are encoded according to textbook RSA (null padding).
- The server knows the secret key  $d$  and
  - uses after decryption only the least significant 128 bits without validating the null-padded bits, meaning that the server does not recognize if there is something there other than zero.
  - An error message is prompted if the encryption attempt results in an “incorrect” session key (decrypted text cannot be interpreted by the server). In all other cases there will be no message.

Idea for attack: Approximation of  $Z$  in 129 bits from the equation  $N = M * Z$  per  $M = \lfloor N/Z \rfloor$

All bit positions for  $Z$  are successively calculated: for each step the attacker gets one additional bit. He or she then modifies  $C$  to  $C'$  (see below). If a bit overflow occurs while calculating  $M'$  on the server (recipient), the server sends an error message. Based on this information, the attacker can determine a single bit of  $Z$ .

## Mathematics: Attacks on RSA using lattice reduction

**Attack on small secret exponents (according to Bleumer / May)**

**Description**  
This attack allows to factor an RSA modulus  $N$ , in case the secret key  $d$  is chosen too small compared to  $N$ . The number  $\delta = \log(d)/\log(N)$  is called "size of  $d$ ". The attack is feasible for  $\delta < 0.290$ .

☐ To apply examples from the literature, first enter the public key  $(N, e)$ . Then enter the estimated value of  $\delta$ . Alternatively, you can directly enter  $d$  to calculate  $\delta$ .

☒ To generate random values, enter the desired  $\delta$  and bit length of  $N$ . Then click on "Generate random RSA key".

Then click "Start".

**Step 1: Enter key parameters and key**

Bit length of:  delta:

$N$ :

$e$ :

$d$ :

**Step 2: Enter attack parameters for the lattice base reduction**

$m$ :  Determines the size of the lattice to reduce and the maximum size of  $\delta$ . Should be at least 4.

$t$ :  Optimally calculated as a function of  $m$ .

Lattice dimension:  Size of the lattice to reduce. Impacts the running time significantly.

Maximum delta:  Maximal size of  $\delta$  for big  $N$  ( $N > 1000$  Bit).

**Step 3: Start attack**

Building lattice:

Reducing lattice:  Reductions:

Calculating resultant:  Resultants:

Overall time:

Found factorization:

$p$ :   $q$ :

- Demonstrates that the parameters of RSA should be chosen to withstand the lattice reduction attacks described in current literature.
- **3 variants** which are *not* resistant:
  1. The secret exponent  $d$  is too small in comparison to  $N$ .
  2. One of the factors of  $N$  is partially known.
  3. A part of the plaintext is known.
- These assumptions are realistic.

**Secret Sharing: Initializing the threshold scheme**

By means of a  $(t, n)$  Shamir scheme a secret  $S$  can be distributed among  $n$  persons. Afterwards,  $t$  persons ( $t \leq n$ ) will be able to reconstruct the original secret by combining their individual secrets (shares). To set up such a scheme, a polynomial  $f(x)$  of degree at most  $t-1$  [with  $t-1$  coefficients  $a(i)$  chosen at random] and a random prime  $p$  must be generated. Each participant receives a randomly chosen public value  $x$  and his or her share, the corresponding secret value  $y=f(x)$ . Each prime  $p$  passes a test that results from Fermat's [Little Theorem](#):  
For  $b \in \{2, \dots, p-1\}$ , test if  $b^{p-1} \equiv 1 \pmod{p}$ .

This test is called **Fermat Test**. Unfortunately some composite numbers pass it as well.

Example:  $341 = 11 \cdot 31$ , and yet  $2^{340} \equiv 1 \pmod{341}$ .

Passing the test provides no information. It must be repeated with a different base  $b$ :

$n =$    $2^{n-1} \equiv 1 \pmod{n}$  Test passed  
 $\text{GCD}(b, n) = 1$    $b$

**Definition:** Let  $n$  be a composite number coprime to  $b$ .  
If  $b^{n-1} \equiv 1 \pmod{n}$ , then it is said that

- $n$  is **pseudoprime to  $b$** ,
- and
- $b$  is a **liar for** (the primality of)  $n$ ,

otherwise it is said that

- $b$  is a **witness against** (the primality of)  $n$ .

**Theorem:** If there are any witnesses against  $n$ ,  
then they make up at least 50% of all  $b \in \{1, \dots, n\}$  coprime to  $n$ . [Proof](#)

# Examples (22)

## Password quality meter (PQM) (2)

### Insights from the Password Quality Meter

- Password quality depends primarily on the **length of the password**.
- A higher quality of the password can be achieved by using **different types of characters**: upper/lower case, numbers, and special characters (**password space**)
- **Password entropy** is an indicator of the randomness of the password characters within the password space (higher password entropy results in improved password quality)
- Passwords should **not exist in a dictionary** (remark: a dictionary check is not yet implemented in CrypTool).

### Quality of a password from an attacker's perspective

- Attack on a password (if any number of attempts are possible):
  1. Classical **dictionary attack**
  2. Dictionary attack **with variants** (e.g., 4-digit number combinations: "Summer2007")
  3. **Brute-force attack** by testing all combinations (with additional parameters such as limitations on the types of character sets)
- ⇒ A good password should be chosen so that attacks 1 and 2 do not compromise the password. Regarding brute-force attacks, the most important factors are the length of the password (recommended at least 8 characters) and the character set that was used.

### Menu Lattice Based Attacks on RSA (Menu [Individual Procedures](#) \ RSA Cryptosystem)

The menu **Lattice Based Attacks on RSA** contains the following commands:

[Factoring with a Hint](#) Attacks RSA with lattice reduction algorithms, if a part of one of the primes of  $N$  is known.

[Attack on Stereotyped Messages](#) Attacks RSA with lattice reduction algorithms, if a part of the original cleartext of an intercepted ciphertext is known and if  $e$  is small.

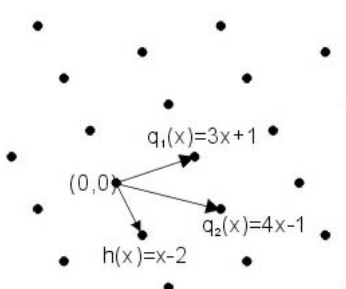

[Attack on Small Secret Keys](#) Attacks RSA with lattice reduction algorithms, if  $d$  is too small compared to  $N$ .

All attacks presented here are based on a common approach: first the task of breaking RSA is transformed into finding the root of a polynomial modulo an integer (mostly  $N$ ) but to find such a root is a difficult problem.

To solve this problem further polynomials are generated which are known to have the same root. From the coefficients of these polynomials a latticebase is built. This is then reduced with, i.e. the LLL-algorithm to find a small vector.

From this newly found short vector a new polynomial is built. It can be proven that if the vector is short enough, the polynomial has the desired root not only modulo  $N$ , but also over the integers.

**Example:**

The polynomial  $q_1(x) = 3x+1$  has a root  $x_0$  modulo 7. It is supposed, that the polynomial  $q_2(x) = 4x-1$  has the same root  $x_0$  modulo 7. From these polynomials the vectors  $b_1 = [3 \ 1]$  and  $b_2 = [4 \ -1]$  are built. All integer linear combinations of these vectors form points in a lattice. The Figure on the left shows a part of this lattice. Each point of the lattice now can again be interpreted as a polynomial having the desired root. A short vector of the lattice is  $b_3 = [1 \ -2]$  from which the polynomial  $h(x) = x-2$  is built. this polynomial has a root in  $x_0=2$  over the integers as well als modulo 7. That  $x_0=2$  is also a root of the polynomials  $q_1(x)$  and  $q_2(x)$  modulo 7 can be easily established.

$(3x_0+1=7, \ 7 \text{ modulo } 7 = 0)$

### Comparison of Base64 and UU encoding

The encoding procedures of [Base64](#) and [UUencode](#) are quite similar, which is shown by the following figure:

**Base64**      **UUencode**

Dividing of 3 x 8 bit to 4 x 6 bit.

Byte 1      Byte 2      Byte 3

7 6 5 4 3 2 1 0    7 6 5 4 3 2 1 0    7 6 5 4 3 2 1 0

Character 1      Character 2      Character 3      Character 4

Step 1: Splitting the data stream -- same procedure in both encodings.

Step 2: Representation of the 6 bit values -- different procedures.

Get the characters from Base64 coding table. (defined in an IETF standard)

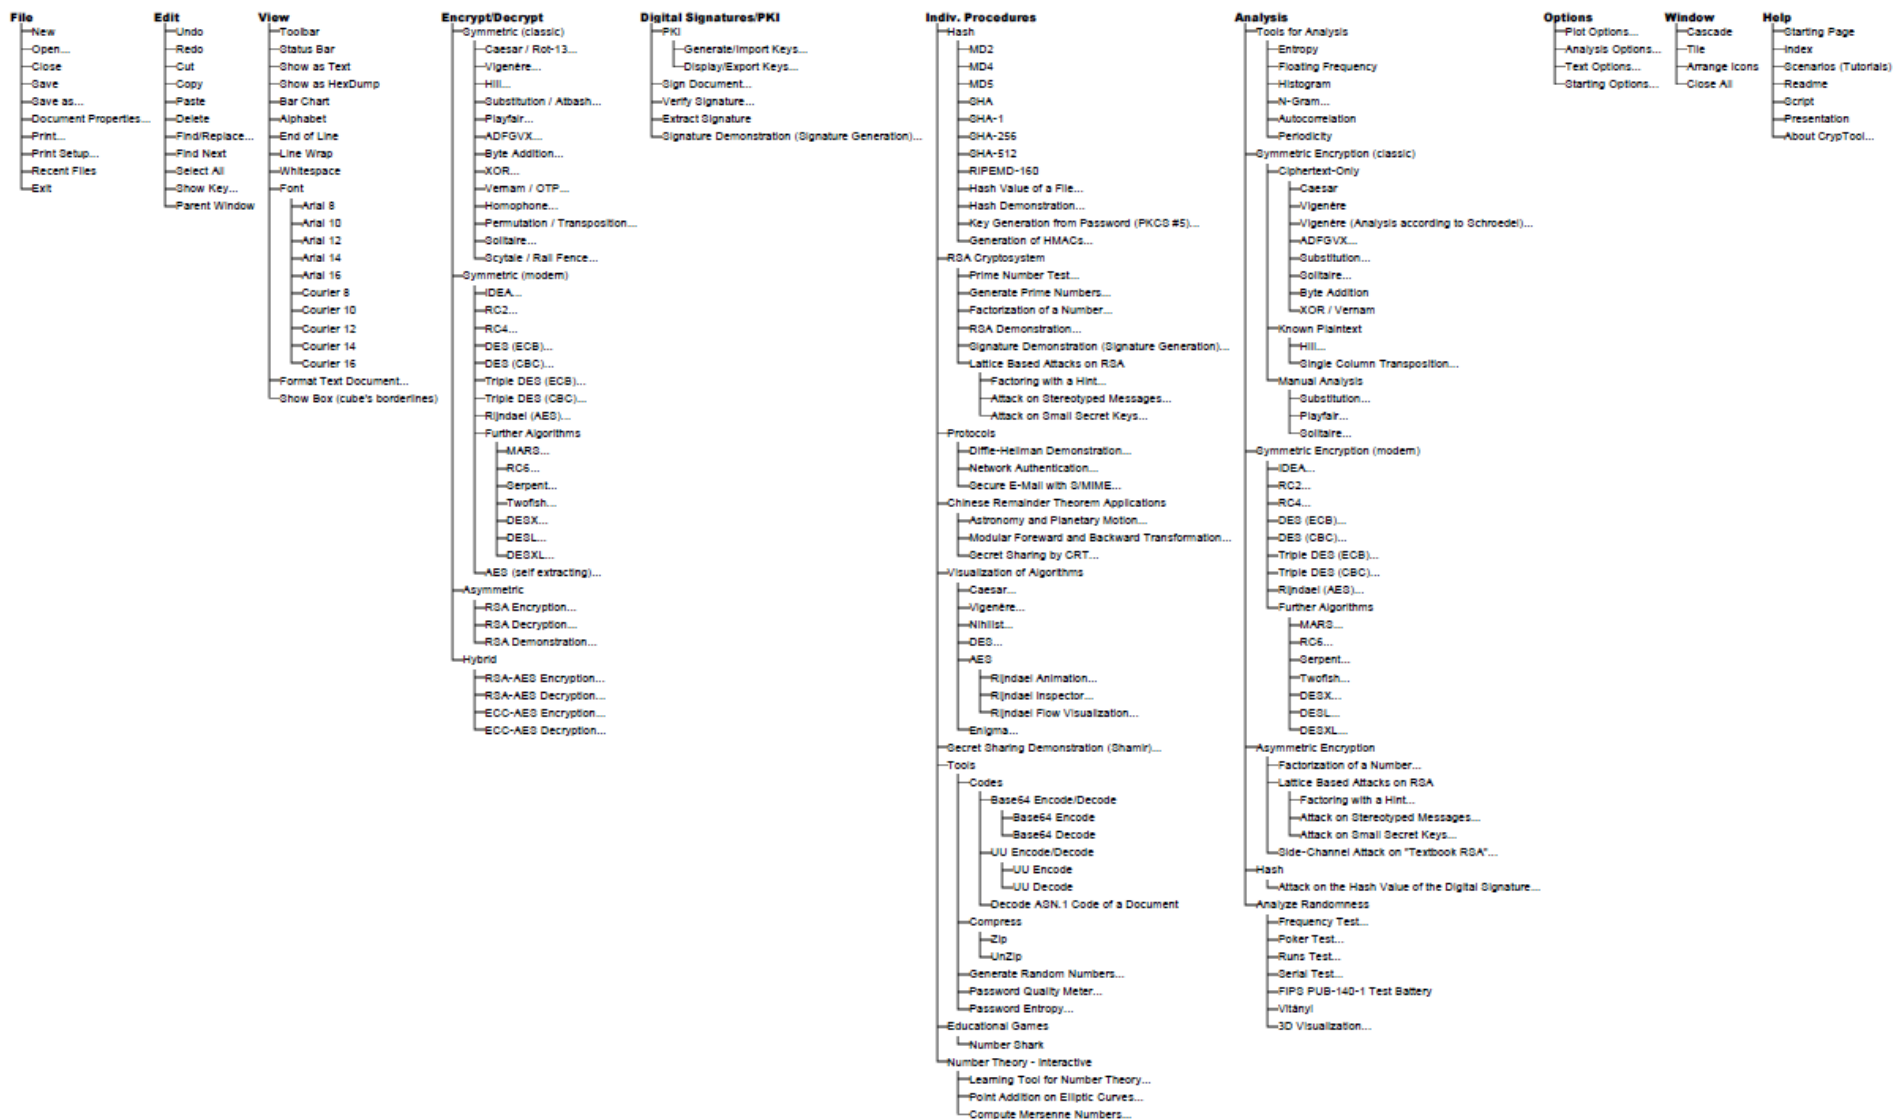

Get the characters, increased by decimal 32, from the ASCII char set.

Because of the similar encoding procedure, there are also shared advantages and drawbacks:

Advantages	Drawbacks

## Examples of what is coming after the release of CrypTool 1.4.30 (see readme for details)

CT1	FIPS test with the ability to analyze packets with lengths other than 2500 bytes, etc.
JCT	Tri-partite key agreements
JCT	Visualization of the interoperability between S/MIME and OpenPGP formats
JCT	Entropy analysis
JCT	Fleissner grille, Autokey Vigenère, interactive cryptanalysis of classic ciphers
JCT	Analysis of transposition ciphers using the ACO algorithm
JCT	Visualization of zero-knowledge proofs
JCT	Visualization of Quantum Key Agreement, BB84 protocol
JCT	Visualization of the SETUP attack against RSA key generation (Kleptography)
JCT	Action history with the ability to create and replay any given cipher cascade
CT2	Comprehensive visualization on the topic of prime numbers
CT2	GNFS (General number field sieve)
CT2	Encryption and automated cryptanalysis of the Enigma machine (and possibly of Sigaba as well)
CT2	Cube attack (I. Dinur and A. Shamir: "Cube Attacks on Tweakable Black Box Polynomials", 2008)
CT2	Demonstration of Bleichenbacher's and Kuehn's RSA signature forgery
CT2	Demonstration of virtual credit card numbers (as an educational tool against credit card abuse)
CT2	WEP encryption and WEP analysis
CT2	Mass pattern search
CT2	Framework for distributed cryptanalysis
CT2	Demonstration of SOA security (SOAP messages with WS-Security)
CT2	Framework to create and analyze LFSR stream ciphers
CT2/JCT	Creation of a command-line interface for batch processing
CT2/JCT	Modern pure plugin architecture with plugin reloading capability
All	Expanded parameterization and flexibility of present algorithms
Ideas	Visualization of the SSL protocol // Demonstration of visual cryptography

# Future CrypTool Development (2)

## In Progress: the two successor versions of CT v1 (see readme file)

1. JCT: Port and redesign of CrypTool in Java / SWT / Eclipse 3.6 / RCP
  - see: <http://jcryptool.sourceforge.net>
  - Release Candidate RC3 is available since July 2010.
2. CT2: Port and redesign of the C++ version with C# / WPF / VS2010 / .NET 4.0
  - direct successor of current release: allows visual programming, etc.
  - Download from: <http://cryptool2.vs.uni-due.de/index.php?page=14&lm=1&q1=4>
  - Beta 3 is available since August 2010 (since July 2008, betas are continuously updated, nightly builds).

JCryptTool (JCT)

# CrypTool as a Framework

## Proposal

- Reuse the comprehensive set of algorithms, included libraries, and interface elements as a foundation.
- Free training to help get started with CrypTool development.
- Advantage: code written for university theses or other projects will not simply disappear, but rather be further maintained.

## Current development environment for **CT1**: Microsoft Visual Studio C++ , Perl, Subversion Source Code Management

- CrypTool 1.4.30: Visual C++ .NET (= VC++ 9.0)(= Visual Studio 2008 Standard)
- Description for developers: see [readme-source.txt](#)
- Sources and binaries of release versions are available for download.  
To get sources of current betas, please see the Subversion repository.

## Development environments for **CT2** and **JCT**

- CT2 – C# version: .NET with Visual Studio 2010 Express Edition (free) and WPF
- Java – Java version: Eclipse 3.6, RCP, SWT (free)

# CrypTool – Request for Contribution

## Every contribution to the project is highly appreciated

- Feedback, criticism, suggestions, and ideas
- Integration of additional algorithms, protocols, analysis (consistency and completeness)
- Development assistance (programming, layout, translation, testing)
- For the current C/C++ project
- For the new projects (preferred):
  - C# project: “CrypTool 2.0” = CT2
  - Java project: “JCrypTool” = JCT
- In particular, university faculties that use CrypTool for educational purposes are invited to contribute to the further development of CrypTool.
- Samples of open tasks are on the following developer pages:
  - CT2: See the list <http://cryptool2.vs.uni-due.de/>, Volunteer, Open Tasks
  - JCT: See the wiki <http://sourceforge.net/apps/mediawiki/jcryptool/index.php?title=CurrentDevelopment>
- Users that make a significant contributions can request to be referenced by name in the online help, the readme file, the about dialog, and/or on the CrypTool website.
- CrypTool v1 is currently being downloaded over 6000 times per month from the CrypTool website. Just over half of these downloads are of the English version.  
The betas of the two successors are already being downloaded over 1000 times a month each.

**CryptTool Introduction**

The application CryptTool is a free e-learning application for Windows. You can use it to apply and analyze cryptographic algorithms. The current version of CryptTool is used all over the world. It supports both contemporary teaching methods at schools and universities as well as awareness training for employees.

The current version offers beside others the following highlights:

- Numerous classic and modern cryptographic algorithms (encryption and decryption, key generation, secure passwords, authentication, secure protocols, ...)
- Visualisation of several methods (e.g. Caesar, Enigma, RSA, Diffie-Hellman, digital signatures, AES)
- Cryptanalysis of certain algorithms (e.g. Vigenère, RSA, AES)
- Crypt-analytical measuring methods (e.g. entropy, n-grams, autocorrelation)
- Auxiliary methods (e.g. primality tests, factorisation, base64 coding)
- Tutorial about number theory
- Comprehensive online help
- Supportive script with further information about cryptology

From its original use of information security training for a company, CryptTool has developed into an outstanding open source project for cryptology related topics.

Since spring 2008, the CryptTool project has been operating the [Crypto Portal for Teachers](#). Thus far, the portal

## CryptTool-Mobile

CryptTool-Online optimized for smart phones

CryptTool-Online provides an excellent introduction to the world of **cryptology**. A great variety of ciphers, encryption methods and tools are introduced, often together with illustrated examples and explanations, making explanations easy to understand with the goal to further your knowledge in cryptology and cryptanalysis. Therefore, this website provides interactive applets to experiment with the introduced methods and to learn by doing.

You can learn the fundamentals of classic ciphers in a little while (e.g. the Enigma, which significantly affected the world of cryptology during World War II), and also use the tools provided on this website to encrypt and decrypt messages yourself. You can also decrypt and analyze already encrypted messages and learn about the weaknesses of the different ciphers.

CryptTool-Online is the online version of the free e-learning program **CryptTool**. While CryptTool online is primarily intended for studying the fundamentals of classic ciphers, the download version of CryptTool is also suitable for working with longer texts and conducting high performance analyses on encrypted messages.

## FOUR LEVELS OF CHALLENGES

MysteryTwister C3 offers something for everybody by featuring four levels of challenges, from pen-and-paper riddles to highly sophisticated mathematical mysteries.

[Register here](#)

**The three levels**

**Level I Challenges - Pen & Paper**  
Level I challenges are very similar to classroom puzzles from newspapers and can be solved with little cryptographic background. You don't need a computer for solving level I challenges. If you need a little bit of theoretical thinking and probably some paper and a pencil, solving a level I challenge probably rewards the solver within minutes or even seconds. The algorithms needed are usually built into tools of these kind of cryptograms tools available. Hence, if you are a beginner in the area of cryptology (e.g., cipher), but nevertheless interested in this mysterious topic of cryptology, give challenges of level I a try - a feeling of success is almost guaranteed after a very short time.

**Level II Challenges - Programming skills required**  
Level II challenges require some background knowledge in cryptology and usually some computational power. Additionally, the tools needed are most likely not yet or at least not as fast as available in cryptology tools like Cryptool. Therefore, you first need to understand the problems and second you need to write a computer program - which might not be a single forward implementation, in total it might take from hours to days to solve a level II challenge. Hence, if you consider yourself well armed with cryptology knowledge (e.g., being a student participating in a cryptology course at the university), give challenges of level II a try - the feeling of success will not come easy, but it will be worthwhile.

**Level III Challenges - Large amount of computing power could be useful**  
Level III challenges require profound background in cryptanalysis and usually a lot of computational power at your disposition. The problems given in this level represent current research questions which we believe to be highly difficult. Therefore practicable solutions might or might not be available.

### What is MTC3?

**C3?** MysteryTwister C3 (MTC3), successor of the famous [MysteryTwister](#) site, is an international cryptography competition. A variety of tasks and challenges are offered at four levels of difficulty. These challenges can be as easy as deciphering a Caesar cipher (Level I) and as hard as breaking a modern encryption algorithm like AES (Level III). Some of the challenges are still today unsolved (Level X). The various topics covered by the MTC3 challenges are intended to offer a survey of cryptology for everyone. The **four levels** of difficulty in MTC3 offer cryptographic challenges for a student just starting to learn about cryptography as well as for experts with many years of experience and plenty of resources at their disposal.

Mystery Twister C3 (MTC3) is an international crypto challenge contest.
